

Reflection :

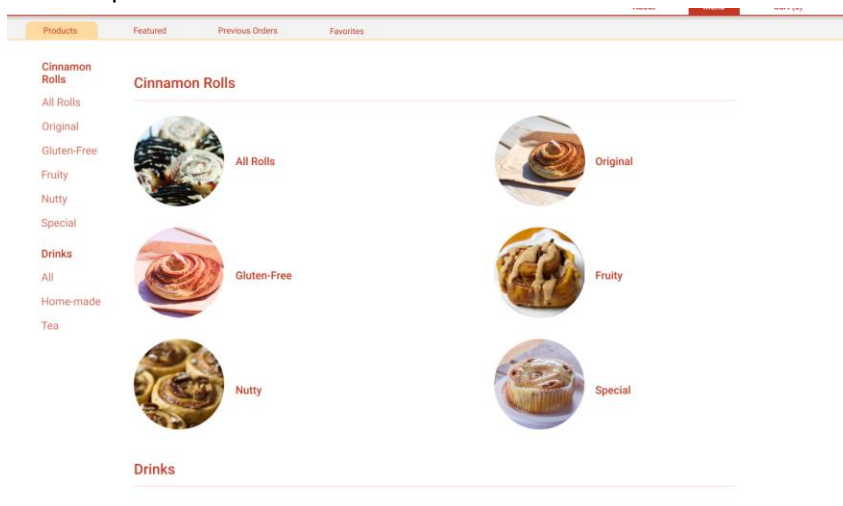

Improvements from last design:

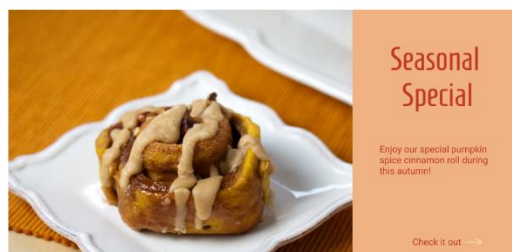

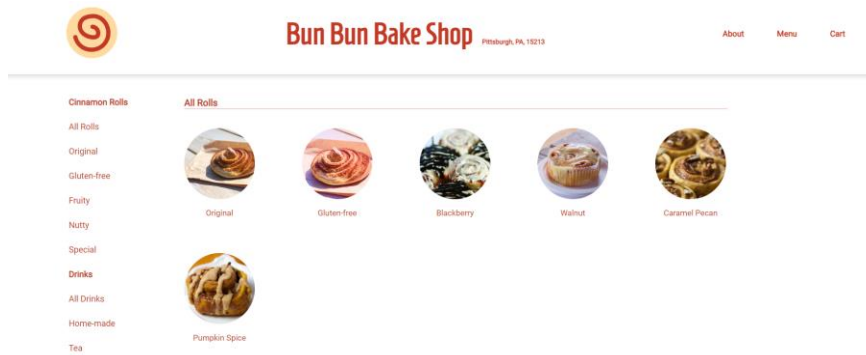

I.

From my Figma design to the actual website, I decided to remove the horizontal navigation bar since there is already a floating side bar on the left and another navigation bar in the header. Too many navigations could make people overwhelmed.

- II. Since we only have a total of 6 products in the cinnamon roll section, at first the product browsing page was designed to be landing a page where the user sees all the categories of cinnamon rolls. But since we only have 6 products, that page is a bit too much (involves more interaction to get to the product detail page). So I deleted that page and instead to directly show all products when users click on menu.

III. I definitely think that the previous design I had the “check it out” is not as prominent as I intended to be, and people can easily miss the hyperlink there. So instead, I made a button and made it more prominent.

Flexible Ordering

Flexible Ordering

Challenges I overcame:

Since this is my first-time coding with html and CSS, at first I was rather confused with margin and padding and wondered how they were different. And I went to YouTube and watched some tutorials, experimented with these two tags on my own with my codes, I started to see the difference and hopefully used them right in my code.

I have also experienced bugs when creating the footer for my product browsing page. I tried so many different ways to change the value in my codes to see what is wrong with the footer and the footer just kept inline with my product gallery. And after about half an hour trying to debug, I found out that it was that I forgot to close the div tag for my product gallery, which explains why, and I believe I can see the root cause of a similar problem immediately when I code later.

I have also experienced issues with web page contents always go off the page. And I fixed that problem by searching in google and found people asking similar questions and solved the problem

by looking at the explanations they give. Apparently I need to use the box-sizing: border box and the problem was solved.

Brand:

Since I am designing for a baker shop, the first thing comes to mind is that the design of the web page should be clear and simple, and features the cinnamon rolls the store has. The color choices should be stimulating appetite while it should also reminds people of cinnamon roll, so I had a warm tone red and orange for the theme colors of the website. I also believe that people who order from this baker shop should either be looking for a breakfast or a snack in the afternoon, which I have also had a promoting section where gives buyers some scenarios of why they should buy these certain amount (say a dozen or half a dozen).
